Document information

Category: Codes and Standards

Keywords: PG&E CASE, Codes and Standards Enhancements, Title 24, nonresidential, 2008, efficiency

Overview

The nonresidential insulation levels were last updated in 1992 and very few changes have been made to the prescriptive envelope requirements in the last 12 years. The main changes came with the Title 24 2005 Standards as U-factors were pre-calculated for all common construction assemblies and published as Joint Appendix IV for both the residential and nonresidential Alternative Calculation Method (ACM) manuals. Another change with the Title 24 2005 Standards applies to metal buildings; the R-value method was eliminated as a compliance option for metal building roofs to achieve equivalent U-factor performance for this construction type compared to other roof types.

The approach in this analysis is to calculate the cost effective level of insulation for separate classes of construction. The analysis is based on time dependent valued (TDV) energy, which replaced source energy with the 2005 update to the Standards. TDV electric energy weights consumption and savings by time of day. TDV gas energy weights consumption by season.

The approach is to identify a list of reasonable constructions for each class of construction; to estimate the cost for each construction assembly, estimate the TDV energy for each construction assembly in the list, and calculate the life-cycle cost of each construction assembly using the CEC approved life-cycle cost methodology.

Description

The proposed change is a modification to the prescriptive insulation requirements for nonresidential buildings, which are contained in Tables 143-A, 143-B, and 143-C. The standards for relocatable school buildings in Table 143-C are for buildings that can be relocated to any climate zone, and so the insulation requirements correspond to those of the most severe climate zones in Table 143-A. Since the prescriptive standards set the baseline for the performance method, the performance method would become more stringent also.

Energy Benefits

The energy benefits are calculated using DOE-2.1E, the California Energy Commission (CEC) reference method for nonresidential buildings. A separate analysis is performed for each opaque construction type (roof, wall, and floor) and class of construction within that type (mass, metal buildings, metal framing and wood framing). The life-cycle cost optimum insulation is determined for each type/class in the sixteen climate zones. The evaluation is performed using a life-cycle cost approach based on TDV energy and the CEC methodology. U-factors taken from construction data listed in Joint Appendix IV are used in the analysis.

Non-energy Benefits

Non-energy benefits from improved insulation levels include improved comfort and environmental benefits - environmental benefits are discussed in the next section.

Environmental Impact

Insulation will reduce heat loss and gain through building envelopes and this will reduce the use of heating and cooling system energy that negatively impacts the environment. The primary environmental impact is the reduction in air emissions from the reduction in furnace or boiler emissions due to reduced heating fuel (natural gas) consumption and power plants due to reduced electricity consumption.¹

¹ The reduction in emissions due to reduced electricity could occur anywhere throughout the Western United States whereas the reduction in emissions due to reductions in heating will occur at the building site.

Type of Change

This report recommends changes to the prescriptive requirements. As the prescriptive standards change, the baseline for performance calculations also changes. The Title 24 Standards and Nonresidential ACM Manual will need to be modified accordingly.

Technology Measures

Measure Availability and Cost

There are numerous manufacturers of insulation products, and products are widely distributed through contractors, wholesale distributors, and retail. The market place for insulation is competitive and healthy. Products being considered in this study are already available in the marketplace, and increasing the minimum insulation requirement should not cause a shortage, if ample time is given before implementation of the requirements so that manufacturers have time to shift production output. Increasing the minimum insulation requirement should not affect the manufacturing process materially.

The cost of insulation is directly related to the quantity that is purchased and installed in the building. Shifting from one type (fiberglass batts) to another (foamed plastic) will change the cost per unit of thermal resistance (R-value). The cost of insulation products is well documented in the literature. More information is provided later in the report on insulation costs, since this is a key input to the analysis.

Performance verification or commissioning of insulation systems is not common in nonresidential buildings. With the 2005 update to the Standards, field verification and diagnostic testing of insulation systems was added as a compliance option for low-rise residential buildings to recognize that research has shown that insulation is commonly installed with construction defects. For low-rise residential buildings, the thermal performance of insulation is assumed to be installed according to standard practice methods unless a HERS rater performs field verification and diagnostic testing to demonstrate that high quality installation has been achieved. This report does not propose a similar approach at this time for basing nonresidential insulation performance on the presence of construction defects unless the work is independently verified to insure a high quality installation is achieved.

Useful Life, Persistence and Maintenance

The life-cycle cost analysis used a 30 year life for insulation. This is the current standard and common practice for envelope requirements. There is no significant persistence or maintenance issues related to increasing insulation levels. The only potential issue is the degradation over time of insulation performance due to the possible condensation of water within a construction assembly. Condensation could result at walls adjacent to moisture laden spaces when there is an inadequate or discontinuous vapor barrier.

Analysis Tools

Energy savings and peak electricity demand reductions can be quantified using the current reference method or approved ACMs.

Relationship to Other Measures

Heating and cooling loads will be impacted by improved insulation levels and heating and cooling systems may possibly be downsized.

Methodology

Approach

A component approach is used for the development of the recommended insulation levels. With this approach, the stringency of each category of construction is determined independently from the others. Construction assemblies addressed in this report are organized by type, class and category, as defined below:

Types The three types of constructions are roofs, walls and floors. These are defined in the standards.

Classes A separate performance criterion is recommended for each class of construction. A class of

construction can be a consolidation of more than one category, as defined in the next bullet.

Categories Categories are consolidated into classes. The categories of construction used in this analysis are

the same as those used to group information in Joint Appendix IV.

A separate life-cycle cost analysis was performed for each category and then the data was consolidated into classes. The construction assemblies considered in the life-cycle cost analysis are those that are included in each table of Joint Appendix IV. The initial cost of each construction assembly was estimated from nationally published data² but cross checked against regional data for California³.

The energy consumption of each construction assembly is calculated for three occupancy types, which capture the principal variation within the occupancy schedules referenced in the nonresidential ACM manual. These include occupancy schedules for daytime only, 24-hour (i.e., highrise residential and hotel/motel), and retail. The schedules of operation, occupant loads, lighting loads, plug loads and other modeling assumptions for these three occupancies are taken from the Nonresidential ACM Manual. Details on these and other modeling assumptions are provided later in this section.

Once the energy use and the initial cost were determined for each construction category, the life-cycle cost is calculated for each construction assembly using the CEC recommended methodology. The approach is to find the construction assembly that minimizes life-cycle cost.

Categories of Construction

The categories of construction used in the analysis are determined from Joint Appendix IV, as shown below. The tables in Joint Appendix IV present the U-factors and other thermal performance data for just about all levels of insulation. The tables are comprehensive and are intended to provide performance data for all levels of insulation. Every cell in the Joint Appendix IV data tables was evaluated. The categories considered are shown below.

Table IV.25 – Standard U-factors for Concrete Raised Floors

Cost Data

Cost assumptions are critically important to the life-cycle cost. The higher the initial cost, the less likely a measure will be cost effective. However, only the incremental cost of adding insulation or otherwise improving the thermal performance of the construction assembly is of significance for each category of construction (see above).

In order to remain consistent, the analysis used data from one source, *Means CostWorks 2005*. However, as a cross reference and check, the Means data was compared to the *2005 Database for Energy Efficient Resources (DEER)*, where data is available from both sources. When more than one insulation product can be used for a particular application, the product with the lowest cost was used. Incremental costs include both material and labor.

Specific values for certain insulation levels and framing sizes that are not available in the Means database was determined by regression analysis. Values determined through regression are italicized. A separate regression analysis was performed for both the material cost and labor cost. For cavity insulation, no regression was performed for labor cost because the cost is assumed to be fixed to the framing size. In other words, all cavity insulation for 2x4 framing have the same labor cost, and all cavity insulation for 2x6 framing have the same labor cost.

The final costs used in the life-cycle cost analysis includes a 1.09 multiplier to adjust the national figures to California and a 30% markup for contractors' overhead and profit. The multiplier and markup is not represented below.

Wall Framing Costs

Wall framing costs were determined by assuming a 10' high wall, which is typical of nonresidential buildings. 16 in. O.C. and 24 in. O.C. framing are compared as separate categories in the analysis, however, the code recommendation used the 16 in. O.C. framing as the basis.

Table 6 - Wood Framing Costs

	Frame Size	Material Cost	Labor Cost	Total Cost	Square Foot Cost	Incremental Cost
16 in. O.C	2x4	3.56	5.5	9.06	0.91	0

	2x12	<mark>9.07</mark>	<u>5.94</u>	<u>15.01</u>	<mark>1.50</mark>	<u>0.79</u>

Wall framing is assumed to be 10' high as the least cost to the contractor.

CostWorks description: wood framing, partitions, standard & better lumber, 10' high, includes single bottom plate and double bottom plate, excludes waste

Table 7 – Metal Framing Costs

	Frame Size	Material Cost	Labor Cost	Total Cost	Square Foot Cost	Incremental Cost
16 in. O.C.	2x4	13.25	8.45	21.7	2.17	0
	2x6	16.65	8.55	25.2	2.52	0.35
	2x8	20.5	8.7	29.2	2.92	0.75
	2x10	<mark>24.04</mark>	<mark>8.96</mark>	<mark>33.00</mark>	<mark>3.30</mark>	<mark>1.13</mark>
	2x12	<mark>27.65</mark>	9.17	<mark>36.83</mark>	<mark>3.68</mark>	<mark>1.51</mark>
24 in. O.C.	2x4	9.6	6.1	15.7	1.57	0
	2x6	12.1	6.25	18.35	1.835	0.265
	2x8	14.95	6.35	21.3	2.13	0.56
	2x10	<mark>17.52</mark>	<u>6.57</u>	<mark>24.10</mark>	<mark>2.41</mark>	<mark>0.84</mark>
	2x12	<mark>20.17</mark>	<u>6.75</u>	<mark>26.92</mark>	<mark>2.69</mark>	<u>1.12</u>

Wall framing is assumed to be 10' high as the least cost to the contractor.

CostWorks reference: partition, galv LB studs, 18 ga, 10' high, incl galv top & bottom track, excl openings, headers, beams, bracing & bridging

Roof Framing Cost

Attic roof framing costs were excluded from the calculation because additional insulation may be added to the attic without altering the framing. Rafter roof framing costs were determined by assuming a square foot of framing and applying the framing factor specified in the Title 24 2005 Standards, 10% for 16 in. O.C. and 7% for 24 in. O.C. The same process was used to determine costs for metal rafter roofs. 16 in. O.C. and 24 in. O.C. framing are compared as separate categories in the analysis, however, the code recommendation used the 16 in. O.C. framing as the basis.

Table 8 - Wood Rafters Roof Costs

Framing Size	Material Cost	Labor Cost	Total Cost	16" Total Cost	24" Total Cost	16" Incremental Cost	24" Incremental Cost
2x6	3.21	3.30	6.51	0.65	0.46	0	0
2x8	4.96	3.48	8.44	0.84	0.59	0.19	0.13
2x10	7.05	<mark>4.35</mark>	<mark>11.4</mark>	1.14	0.80	<u>0.49</u>	0.34
2x12	<u>9.60</u>	<u>5.22</u>	<mark>14.83</mark>	<u>1.48</u>	1.04	<u>1.83</u>	<u>1.58</u>
2x14	12.96	<mark>6.09</mark>	<u>19.05</u>	1.90	1.33	<u>0.87</u>	<u>0.87</u>

Roof framing is determined by multiplying the total square foot framing cost by the framing factor of 10% for 16 in. O.C. and 7% for 24 in. O.C.

CostWorks description: rafters, roof framing, to 14 in 12 pitch

Table 9 – Metal Rafter Roof Costs

Framing Size	Material Cost	Labor Cost	Total Cost	16" Total Cost	24" Total Cost	16" Incremental Cost	24" Incremental Cost
2x6	5.6	3.43	9.03	0.90	0.63	0	0
2x8	6.2	3.65	9.85	0.99	0.69	0.09	0.06
2x10	7.55	3.91	11.46	1.15	0.80	0.25	0.17
2x12	8.3	4.22	12.52	1.25	0.88	0.35	0.25
2x14	<mark>9.28</mark>	<u>4.46</u>	13.74	<mark>1.37</mark>	0.96	<u>0.47</u>	<u>0.33</u>

Roof framing is determined by multiplying the total square foot framing cost by the framing factor of 10% for 16 in. O.C. and 7% for 24 in. O.C.

CostWorks description: boxed ridge beam, for CF metal rafters, w/ galv joist & track, double, 18 ga

Floor Framing Cost

Floor framing costs were excluded from the calculation because additional insulation may be added to the floor without altering the framing.

Cost Adjustments

The cost is adjusted for California and a markup is added for the contractors' overhead and profit.

The Means data either specifies a national average or a local city average cost; however, the Means data does not provide a weighting factor for the State of California as a whole. In order to determine a reasonable California adjustment factor, we specified a representative city for each of California's sixteen climate zones. Next, we determined the local adjustment factor for each city and weighted the adjustment factor against the percentage of new construction for the representative city and climate zone. The cost adjustment factors were taken from the Means data and the new construction weighting percentages were taken from the 2005 Title 24 Impact Analysis⁴ using the nonresidential new construction database. Table 10 shows the representative city, local adjustment factor, and weighting factor for each of the sixteen climate zones. The weighted markup for each climate zone was determined by multiplying the percent floor area by the local markup. The California adjustment factor or total markup is the sum of the weighted markup.

Energy Use for Each Construction Assembly

The energy use for each construction assembly was calculated using the DOE-2.1E reference method. For each construction type, one or more sets of computer runs were made to establish the relationship between changes in U-factor and TDV energy. The runs include three points that represent high, medium and low U-factors that correspond to no insulation, some insulation (similar to that of the current Standard), and full insulation. The exact DOE-2 inputs can be found in Table 12 through Table 14 below. From these runs, a simple equation was developed to give TDV energy use per square foot of surface area.

$TDV = C0 + C1 \times U$ -factor

where:

C0: constant

C1: coefficient

U-factor: U-factor is the overall heat transfer coefficient for the assembly including both the inside and

outside air film resistance taken from Joint Appendix IV.

The constants and coefficients, along with the R² for the coefficient can be found in Table 22 – TDV DOE-2 Coefficients of the Appendix. Separate coefficients are calculated for each of three occupancy types and sixteen climate zones. For each of these cases, light and heavy mass constructions were considered. For roofs, constructions with and without attics were considered. In all, six different conditions were considered. The six models were put through a DOE-2 simulation and hourly TDV factors were applied. Then a regression was performed on the results determining the wall constant and coefficient for each climate zone and each occupancy in TDV. After the constant and coefficient were determined, the U-factor was applied to the TDV equation above to determine TDV energy use.

Energy Model and Assumptions

DOE-2.1E version 119 developed by Lawrence Berkeley Laboratory was used to create a database of heating and cooling energy for a wide variety of inputs. For all cases, a simple five-zone model was used. The arrangement for thermal zoning was intentionally designed so that perimeter zones are connected only to the interior zone and not to other perimeter zones. This tends to isolate solar effects on the building. Windows are modeled only on each perimeter zone.

A set of C coefficients is developed for each class of construction and fenestration, climate zone and occupancy type. These are important factors in the energy model:

Geometry

- o A 5-zone model
- o Four exterior zones (100 ft X 15 ft) with windows on the long facades, no skylights
- One interior zone (100 ft X 100 ft) without windows
- Space height 13 ft
- Fenestration: The fenestration is set to 30% for daytime and 24-hour occupancy and 10% for retail occupancy. The fenestration used is DOE-2 code 2204: double tint bronze with a U-factor of 0.48 and a SHGC of 0.49

Figure 1 - Five-Zone DOE-2 Model

Internal loads

Table 11 - Internal Loads

Internal Gain	Daytime	Retail	24-hour
Lighting Power Density	1.25	1.5	0.50
Equipment Power Density	0.75	0.94	0.50
Occupancy	29 persons / 1,000 ft ²	29 persons / 1,000 ft ²	5 persons / 1,000 ft ²

HVAC systems

- One packaged single zone (PSZ) system for each zone. No plenum.
- o Cooling EER 9.5, fan power at 0.35 W/cfm

- o Integrated air-side economizer
- Outside air 15 cfm
- o Heating temperature is set to 70°F; cooling temperature is set to 73°F
- o Electricity is used cooling and gas is used for heating
- Operation schedules
 - o Daytime only (typical for office buildings). Annual operating hours 4300
 - o Retail (typical for retail stores). Annual operating hours 5475
 - o 24-hour (typical high-rise residential). Annual operating hours 8760

Life Cycle Cost Model

The CEC life-cycle cost method⁵ was used. Measures are assumed to have a 30 year life and the TDV net present values for 30 years were used in this analysis.

This is summarized in the following equation:

$LCC = Initial_Cost + PV_{TDV} \times TDV$

where:

LCC: life cycle cost in dollars

Initial Cost: incremental cost of the construction assembly from the base case

PV_{TDV}: net present value of TDV which is determined to be 0.129 for 30-year nonresidential measures

TDV: annual electricity use for HVAC fan, cooling and heat per square foot of construction (wall, roof or

floor) area.

⁵ Life Cycle Cost Methodology, 2008 California Building Energy Efficiency Standards

Nonresidential Insulation Requirements CASE Report

Results

2005 versus 2008 Insulation Level Comparisons

The tables below provide a comparison between the current standard and the proposed standard for certain representative climate zones. For both roofs and walls, the proposed standard is usually more stringent than the current standard. This may be due to the Commission's policy to use a longer building life expectancy of 30-years for envelope measures, a change in the cost of natural gas and electricity TDV energy, and a change in insulation price since 1992, the latest update to the envelope criteria.

Cost-effectiveness

A spreadsheet listing the life-cycle cost values for all evaluated construction assemblies can be found at the http link below. The spreadsheet is split by class of construction and can be sorted by the following descriptions:

http://www.archenergy.com/downloads/pub/sf/lcc envelope results.xls

Table 15 – Life-cycle Cost Spreadsheet Definitions

Column	Definition
Occupancy	Occupancy Type (Daytime, 24-hour, retail)
CZ	Climate Zone (1-16)
Туре	Type of Construction (roof, wall, floor)
Class	Class of Construction (wood, metal, metal building, mass, etc.)
Category	Category of Construction (heavy mass, light mass, 16" o.c., 24" o.c., etc.)
Cavity R	Cavity R-value (non-rigid insulation)
Sheathing R	Sheathing R-value (rigid insulation)
U-factor	U-factor of combined cavity and sheathing R-value (U-factor)
LCC	Life-cycle cost
Rank	Rank (Rank=1 is the lowest life-cycle cost among class and category of construction)
Class and Category	Class and category of construction combined

Note: The column and definition used in this table and the corresponding spreadsheet may be different than the definitions used in the rest of the report; however, the definition should still be self-explanatory.

Recommendations

These are the recommended code changes based on the TDV life-cycle cost analysis. Since the U-factors were used from Joint Appendix IV to calculate the life cycle cost, we recommend that only the U-factors be listed for compliance purposes in the Standards. As long as the construction meets the U-factor requirement, it does not matter whether the requirement is met through non-rigid insulation, rigid insulation, or a combination thereof.

The recommended classes of construction are as follows:

- Roofs: Metal Building, Insulation Above Deck, and Wood-framed and Others
- Walls: Metal Building, Metal-framed, Mass Light, Mass Heavy, and Wood-framed and Other
- Floors: Mass and Other

The ACM Requirements for mass walls specify different types of mass walls as the base case for each climate zone. During the life cycle cost analysis, the mass wall that was specified in the ACM was used.

Proposed Standards Language

The proposed changes to the Standards are the substitution of the tables shown above for Tables 143-A and 143-B and the addition of a new Table 143 for retail occupancies. Table 143-C would be changed to include the new values for the most severe climate zone to allow for relocatable school buildings to be located throughout the state.

Alternate Calculation Manual

Table N2-1 of the nonresidential ACM will need to be modified to reflect the choices from Joint Appendix IV that are recommended.

Acknowledgments

The Pacific Gas and Electric Company sponsored this report as part of its CASE (Codes and Standards Enhancement) project. Steve Blanc of PG&E was the project manager for this nonresidential CASE project. Pat Eilert is the program manager for the CASE program. The HESCHONG MAHONE GROUP is the prime contractor and provided coordination of the nonresidential CASE reports. The research contained in this report was carried out by Tianzhen Hong, Charlie Yu and Charles Eley of Architectural Energy Corporation.

Appendices

Energy Coefficients

TDV energy per square foot of opaque surface area is calculated through regression analysis, using the coefficients in the following table. The coefficients are calculated for all 16 climate zones and all three occupancy types (daytime, 24-hour, and retail). Details of the models used for the three occupancy types are provided earlier in the report. Coefficients are calculated separately for floors, roofs and walls and for each of these

Construction Categories and How They Relate to the Proposed Criteria

The following tables show the lowest life-cycle cost determined for each construction after professional judgment has been applied. The table lists the climate zone grouping and occupancy type. In each cell, the U-factor is given as well as the joint appendix reference for a particular table. For example, in Table IV.1 Day, 1, you will find the values 0.038 and A6. Day refers to daytime occupancy, 1 refers to the climate zone, 0.038 is the U-factor, and A6 is the column and row of the construction assembly found in Table IV.1. For Table IV.12, the cell contains two Joint Appendix references that are more detailed. For example, 12A9 on the second line represents the construction type and refers to Table 9, Column A, and Row 9. Similarly, 19E1 on the third line represents the insulation value and refers to Table 19, Column E, and Row 1.

Comment

Life-Cycle Cost

None

The constructions in this table have to comply with the criteria developed based on Table IV.1. It would be difficult for a building with this type of construction for the whole building to comply with the prescriptive requirements. Most buildings only have a small area of this category of roof construction and compliance could most likely be achieved with the overall envelope tradeoff method, by increasing the insulation of other roof components or other envelope elements.

Table IV.12 – Properties of Hollow Unit Masonry Walls

Two classes of construction (light mass and heavy mass) are recommended for this category of construction. The "Heavy Mass" class includes walls with an HC greater than 15. The "Light Mass" class includes constructions with an HC greater than 7 (which do not qualify as Heavy Mass). All cells in this table qualify as either Heavy Mass or Light Mass.

Life-Cycle Cost

Table IV.13 – Properties of Solid Unit Masonry and Solid Concrete Walls

The criteria developed for Heavy Mass and Light Mass apply for the constructions in this table. Note that Cells A3 and A4 have a HC less than 7. We should either except these constructions, since they are close (6.25 and 6.30) or delete them from the table.

No life-cycle cost analysis.

Table IV.14 – Properties of Concrete Sandwich Panels

The criteria for Heavy Mass apply for all the constructions in this table. All have an HC greater than 15. No life-cycle cost analysis.

Table IV.15 – U-factors for Spandrel Panels and Glass Curtain Walls

The criteria for "Metal Framed" walls applies for the constructions in this table. No life-cycle cost analysis was performed for this category of constructions. No life-cycle cost analysis.
